

What the corridor beam is worth

μ^+ and μ^- counter-rotate, so one straight fires a sign-tagged $\bar{\nu}_\tau$ beam south and a ν_τ beam north, from a flux that is pure muon decay

Rates from tools/tau_compass.py and tools/nutau_sites.py (on-axis point detector, CSMS cross-sections, τ -threshold suppression). Reach uses the chirp as a weighted fit,
 $Z = \varepsilon \sqrt{(MT/f) \sum_i S_i^2 / B_i}$, with OPERA's own τ efficiency and fake rate. Comparison numbers: DONUT PRD 78 052002, OPERA PRL 120 211801, NuTeV PRL 88 091802, DUNE TDR arXiv:2002.03005.
