

The collider in its default aim, and everything around it bearing around, log range radial (each ring also gives the tilt that reaches it); dashed = the 15.40 mrad exit circle

- ★ university partner
- DOE / federal land
- ◆ mine, quarry, far-detector site
- ⬢ Mt. Simon gas storage
- ▲ public land
- population centre
- ✕ airport
- | corridor mark on the meridian
- 15.40 mrad exit circle
- θ_{free} (bearing); shaded = azimuth free
- lake (Natural Earth 10m footprint)
- near beam below 500 ft (north)

Lakes are real footprints projected into this frame; every landmark is placed by its true bearing and range from the IP. The collider's whole 198 km circle lies inside θ_{free} , so at 15.4 mrad the near beam is corridor-bound in every bearing – which is why the study rides the ComEd right-of-way north. Ranges and bearings: static/geo/collider_map.json.
